

ABSTRACT

[105] Secure communication of information in a communication network may comprise acquiring a security code from a second communication device by a first communication device and receiving media containing the security code such as a pin code from the first communication device. The security code may be translated into an IP address corresponding to the second communication device. The received media may be routed to the second communication device based on the IP address of the second communication device. In this regard, the IP address of the second communication device remains anonymous or unknown to the first communication device. A duration for which the security code is valid may be limited to a specific time period and/or for a particular number of uses. Notwithstanding, the security code may be acquired out-of-band.
